

64 K × 4 Static RAM with Separate IO

Features

- High speed
 - 15 ns
- CMOS for optimum speed/power
- Low active power
 - 860 mW
- Low standby power
 - 55 mW
- TTL-compatible inputs and outputs
- Automatic power down when deselected
- Available in Pb-free 28-pin Molded SOJ package

Functional Description

The CY7C192 is a high performance CMOS static RAM organized as 65,536 × 4 bits with separate IO. Easy memory expansion is provided by active LOW Chip Enable ($\overline{CE}$) and tri-state drivers. It has an automatic power down feature that reduces power consumption by 75% when deselected.

Writing to the device is accomplished when the Chip Enable ($\overline{CE}$) and Write Enable ($\overline{WE}$) inputs are both LOW.

Data on the four input pins (I_0 through I_3) is written into the memory location specified on the address pins (A_0 through A_{15}).

Reading the device is accomplished by taking the Chip Enable ($\overline{CE}$) LOW while the Write Enable ($\overline{WE}$) remains HIGH. Under these conditions, the contents of the memory location specified on the address pins appears on the four data output pins.

The output pins stay in high impedance state when Write Enable ($\overline{WE}$) is LOW or Chip Enable ($\overline{CE}$) is HIGH.

A die coat ensures alpha immunity.

Notes

1. Minimum voltage is equal to -2.0 V for pulse durations of less than 20 ns.
2. T_A is the case temperature.
3. Tested initially and after any design or process changes that may affect these parameters.

Notes

- Test conditions assume signal transition time of 3 ns or less, timing reference levels of 1.5 V, input pulse levels of 0 to 3.0 V, and output loading of the specified I_{OL}/I_{OH} and 30-pF load capacitance.
- At any temperature and voltage condition, t_{HZCE} is less than t_{LZCE} , t_{HZWE} is less than t_{LZWE} for any given device. These parameters are guaranteed by design and not 100% tested.
- t_{HZCE} and t_{HZWE} are specified with $C_L = 5$ pF as in part (b) of [Figure 2](#). Transition is measured ± 500 mV from steady-state voltage.
- The internal write time of the memory is defined by the overlap of $\overline{CE}$ LOW and $\overline{WE}$ LOW. Both signals must be LOW to initiate a write and either signal can terminate a write by going HIGH. The data input setup and hold timing must be referenced to the rising edge of the signal that terminates the write.

Figure 4. Read Cycle No. 2 [8, 10]

Figure 5. Write Cycle No. 1 ($\overline{WE}$ Controlled) [11]

Notes

8. $\overline{WE}$ is HIGH for read cycle.
9. Device is continuously selected, $\overline{CE} = V_{IL}$.
10. Address valid prior to or coincident with $\overline{CE}$ transition LOW.
11. The internal write time of the memory is defined by the overlap of $\overline{CE}$ LOW and $\overline{WE}$ LOW. Both signals must be LOW to initiate a write and either signal can terminate a write by going HIGH. The data input setup and hold timing must be referenced to the rising edge of the signal that terminates the write.

Switching Waveforms (continued)

Notes

12. The internal write time of the memory is defined by the overlap of $\overline{\text{CE}}$ LOW and $\overline{\text{WE}}$ LOW. Both signals must be LOW to initiate a write and either signal can terminate a write by going HIGH. The data input setup and hold timing must be referenced to the rising edge of the signal that terminates the write.
13. If $\overline{\text{CE}}$ goes HIGH simultaneously with $\overline{\text{WE}}$ HIGH, the output remains in a high impedance state.
